Supplementary Fig. 1 Machine learning workflow for biomarker identification and validation.

Datasets: Full-16S – full length 16S rRNA gene amplicons sequencing; RNA – metatranscriptomics; MGX – metagenomics.

a

Step	Challenges addressed	Comparison to standard protocol	Advantages	Disadvantages
Sampling technique	Maximizing input mass; addressing difficulties in collecting sufficient biofilm material due to low biomass in healthy patients.	Both paper points and curette were used	Input mass increased, input for cDNA synthesis increased if applicable	Both attached and non-attached cells analyzed
Sample preservation	Preventing degradation of nucleic acids during handling and transport	Storage in RNAprotect at -80°C	Improved sample handling in clinics, long term storage (e.g., multiple yrs) possible	Potential batch effects
Cell lysis	Releasing of both DNA and RNA from low-biomass samples while avoiding degradation of RNA and ensuring effective lysis of biofilm cells	Our combined moderate mechanical-enzymatic lysis outperformed a TRIzol-based approach by 50%	Extraction of DNA and RNA suitable from low input and same starting material for downstream application, minimizing degradation of RNA, which is more fragile.	Underrepresentation of hard-to-lyse taxa representing classes Actinobacteria, Clostridia and Coriobacteria
Separation	Preventing co-purification of unwanted substances which may interfere with isolation of nucleic acids	QIAshredder columns were used for separation	Paper points debris removed	Potential batch effects
Co-isolation	Achieving simultaneous purification of DNA and RNA which avoids batch effects introduced by multiple sampling	Washing DNA from RNA isolation column in first RNA purification step	Co-isolation of DNA and RNA suitable for downstream application, minimizing batch effects introduced by independent sampling	This protocol is favoring RNA, low DNA yields suitable for amplicons sequencing but not for metagenomics potential batch effects
Quality control	Detecting and quantifying contamination in small biofilm samples. Ensuring consistent RNA quality for transcriptomic applications.	Bioanalyzer profiles generated for all the samples at multiple steps (RNA, mRNA, cDNA, pools), with additional technical replicates is applicable, introduction of blank samples and correlation analysis for identification of contaminating taxa	Improved design of pooled cDNA samples, identification and removal of contaminating taxa	Higher resource consumption, potential removal of false negative contaminating taxa
mRNA sample pooling	Maximizing input mass addressing difficulties in extracting sufficient mRNA material due to low biofilm biomass	mRNA pooling by patient and diagnosis in low biomass healthy samples	Higher yield of cDNA	Averaging profiles for multiple implants but presence of individual DNA profiles allows controlling
Re-sequencing	Maintaining sufficient sequencing depth for low-biomass samples.	Re-sequencing of samples with lowest sequencing depth	Increased sequencing depth	Increased costs
Summary	Co-isolation of DNA and RNA from dental implants samples can be challenging especially from healthy patients with little biofilms	We created tailored protocol addressing multiple challenges	Our protocol co-isolates DNA and RNA samples suitable for downstream amplicons and RNA sequencing	Our protocol is time and cost consuming and may introduce some batch effects

b

c

Supplementary Fig 2. Optimized co-isolation of DNA and RNA from peri-implant biofilm samples.

a Table summarizing the key challenges in extracting DNA and RNA from low-biomass biofilm samples and comparison of the optimized protocol with standard extraction approaches. **b** Bar plot and accompanying gels from gel electrophoresis represent the RNA yield obtained from standard samples using different extraction methods. **c** Box and Whisker plot comparing bacterial RNA quantity (calculated as total mRNA multiplied by fraction of reads mapped to bacteria) between healthy and peri-implantitis biofilm samples.

Supplementary Fig. 3 Inter- and Intra-individual variability in the microbiome across samples.

a Bar graph depicting Bray-Curtis similarity at the species and class levels, showing variability within and between technical replicates, different sites within the same patient, and between different patients. **b** Heatmap illustrating the $\log(x + 1)$ normalized relative abundances of species (based on full 16S data, with an abundance cut-off of 0.1% across all samples). Samples are coloured according to their clinical diagnosis group and labelled by the patient of origin. The samples are clustered using the Bray-Curtis similarity matrix, and the colours on the dendrogram represent the group of samples that underwent pooling of RNA counterparts.

Supplementary Fig 4. Separation between diagnosis groups based on genus-level taxa in full-16S training and test (Germany) and metagenomic (Italy) datasets.

a Non-metric multi-dimensional scaling (nMDS) plot based on Bray-Curtis dissimilarity matrices of 16S rRNA gene amplicon data, aggregated to genus level features of the training and two validation set samples. **b** nMDS plot from figure a, samples denoted according to sequencing method (full-16S and MGX) and population (Germany and Italy) **c** genera present in both full-16S and MGX datasets and that showed highest pearson correlation (cut-off ± 0.4) with MDS1 axis. **d** Canonical analysis of principal co-ordinates (CAP) constrained ordination plot of genus level, illustrating the CAP axis that maximizes the separation of the two ‘a priori’ groups based on diagnosis. The performance of the CAP model on the two validation sets shows the successful allocation of validation samples to their respective diagnosis groups. **e** Vector overlays on the nMDS plot show the genera with highest correlation to the CAP1 axis that best separates the diagnosis groups as seen in (d). **f** Relative abundances of the highly correlated genera shown in (c) across diagnosis groups for both full-16S (Germany) and MGX (Italy) sets. T - training dataset, V - validation dataset, Ger – primary study population based on full-16S dataset from Germany; Ita – External validation population based on shotgun metagenomics (MGX) from Italy.

57

58

59

60

6

- 61 are labelled and shown on the left. **e** PCoA ordination plot based on a Bray-Curtis matrix of normalized EC counts associated
- 62 with different amino acid anabolic and utilization pathways. (PERMANOVA p value ≤ 0.0001). Same input as Fig. 5c.

Supplementary Fig. 6. High-resolution view of the curated pathways for selected amino acids based on RNAseq ECs. Anabolic and utilization pathways for **a.** histidine, **b.** arginine, **c.** tryptophan, **d.** tyrosine and phenylalanine, **e.** proline, **f.** threonine, glycine, serine and cysteine, and **g.** methionine were identified using metatranscriptomic data. Colour scale indicates the ‘canonical analysis of principal co-ordinates (CAP)’-based linear discriminant analysis (LDA) correlation of each EC to the CAP1 axis that best separates the diagnosis groups.

Supplementary Fig. 8. Taxon-specific strategies for amino acids metabolism.

a Log 2-fold change plotted for transcriptional anabolic activities of specific bacterial classes against their full amino acid activity. **b** Log 2-fold change plotted for transcriptional catabolic activities of specific bacterial classes against their full amino acid activity. **c** Non-metric multi-dimensional scaling (nMDS) plots depicting amino acid metabolism for 22 genera for specific anabolic and utilization pathways. Vector overlays displaying Pearson's correlations (cut-off > 0.5 or < -0.5) between the amino acid-related pathways and genera plotted in two separate graphs at the bottom right, with longer vectors indicating higher dissimilarity. Bubble sizes reflect % of reads (EC-based) assigned to specific amino acid-related activities. Genera were split by health status (see Fig. 7b).

Supplementary Fig 9. Separation between diagnosis groups based on combined datasets.

Non-metric multi-dimensional scaling (nMDS) plots **a** species + EC4 combination and **b** genus + EC4 combination. Canonical analysis of principal co-ordinates (CAP) plots of **c** species + EC4 combination and **d** genus + EC4 combination, illustrating the CAP1 axis that maximizes the separation of the two ‘a priori’ groups based on diagnosis.

Supplementary Files

A. Demographic and clinical characteristics of the study cohort.

B. Demographic and clinical characteristics of the validation cohort.

C. Full-16S based species level composition. Statistical significance, CAP-based LDA correlation, species-level mean abundances in healthy and peri-implantitis groups

D. Full-16S based genus level composition. Statistical significance, genus-level mean abundances in healthy and peri-implantitis groups

E. Full-16S based class level composition. Statistical significance, class-level mean abundances in healthy and peri-implantitis groups.

F. Metatranscriptome-based features (Enzyme Commission numbers - EC). Statistical significance, CAP-based LDA correlation, Mean 4-digit level EC abundances in healthy and peri-implantitis groups.

G. Metatranscriptome-based class level taxonomic features. Statistical significance, class level mean abundances in healthy and peri-implantitis groups.

H. Curated amino acid metabolism dataset. Mean abundances of ECs aggregated to anabolic and catabolic pathways and their transcribing active taxa.

I. Representative 16S rRNA gene sequences for full-16S taxa designated with OTU numbers.

J. Full-16S and metatranscriptomic sequencing reads per sample

A. Demographic and clinical characteristics of the study cohort
